80 <jats:abstract xmlns:jats="http://www.ncbi.nlm.nih
    .gov/JATS1">
    <jats:p>The influence of SiO2 particles on the
        microstructure, phase composition, corrosion
        and wear performance of plasma electrolytic
        oxidation (PEO) coatings on AM50 Mg was
        investigated. Different treatment durations
        were applied to fabricate coatings in an
        alkaline, phosphate-based electrolyte (1 g/L
        KOH + 20 g/L Na3PO4 + 5 g/L SiO2), aiming to
        control the incorporated amount of SiO2
        particles in the layer. It was found that the
        uptake of particles was accompanied by the
        coating growth at the initial stage, while
        the particle content remained unchanged at
        the final stage, which is dissimilar to the
        evolution of the coating thickness. The
        incorporation mode of the particles and phase
        composition of the layer was not affected by
        the treatment duration under the voltage-
        control regime. The corrosion performance of
        the coating mainly depends on the barrier
        property of the inner layer, while wear
        resistance primarily relies on the coating
        thickness.</jats:p>
